Diagnosis and Treatment of Lichen Planus

Lichen planus is a chronic, inflammatory, autoimmune disease that affects the skin, oral mucosa, genital mucosa, scalp, and nails. Lichen planus lesions are described using the six P’s (planar [flat-topped], purple, polygonal, pruritic, papules, plaques). Onset is usually acute, affecting the flexor surfaces of the wrists, forearms, and legs. The lesions are often covered by lacy, reticular, white lines known as Wickham striae. Classic cases of lichen planus may be diagnosed clinically, but a 4-mm punch biopsy is often helpful and is required for more atypical cases. High-potency topical corticosteroids are first-line therapy for all forms of lichen planus, including cutaneous, genital, and mucosal erosive lesions. In addition to clobetasol, topical tacrolimus appears to be an effective treatment for vulvovaginal lichen planus. Topical corticosteroids are also first-line therapy for mucosal erosive lichen planus. Systemic corticosteroids should be considered for severe, widespread lichen planus involving oral, cutaneous, or genital sites. Referral to a dermatologist for systemic therapy with acitretin (an expensive and toxic oral retinoid) or an oral immunosuppressant should be considered for patients with severe lichen planus that does not respond to topical treatment. Lichen planus may resolve spontaneously within one to two years, although recurrences are common. However, lichen planus on mucous membranes may be more persistent and resistant to treatment. ### Pathophysiology

Although the exact etiology of lichen planus is unknown, an immune-mediated pathogenesis is recognized. Lichen planus can appear at any age, but most cases occur between 30 and 60 years of age.

#### Clinical Presentation

Lichen planus lesions are described using the six P’s (Table 1). Onset is usually acute, affecting the flexor surfaces of the wrists (Figure 1), forearms, and legs. These lesions are often covered by lacy, reticular, white lines known as Wickham striae (Figure 2). The lesions may appear in a linear configuration, following the lines of trauma (Koebner phenomenon; Figure 3). It is common to see postinflammatory hyperpigmentation as the cutaneous lesions clear, especially in persons

Lichen planus is a chronic, inflammatory, autoimmune disease occurring in 0.1 to 4 percent of the general population, most often in perimenopausal women. A meta-analysis of primarily case-control studies conducted in multiple countries found a statistically significant association between hepatitis C virus (HCV) infection and lichen planus, although there is no known explanation for this association. Compared with the control group, patients with lichen planus had a greater prevalence of HCV exposure (odds ratio = 5.4; 95% confidence interval, 3.5 to 8.3), and patients with HCV infection had an increased prevalence of lichen planus (odds ratio = 2.5; 95% confidence interval, 2.0 to 3.1). It is appropriate to screen all patients with lichen planus for HCV infection. Patients should be asked about HCV risk factors, and liver enzyme and HCV antibody tests should be ordered.

with darker skin. Although lichen planus often occurs only on cutaneous surfaces, it may also involve the oral mucosa, genital mucosa, scalp, or nails.6

Cutaneous lichen planus may present in different forms. Linear lichen planus (Figure 3) manifests as closely aggregated linear lesions on the limbs that may develop the Koebner phenomenon. Annular lichen planus (Figure 4) accounts for approximately 10 percent of lichen planus cases.7 It commonly appears as arcuate groupings of individual

papules that develop rings or a peripheral
extension of clustered papules with central
clearing. In addition to the usual sites of
distribution, this form of lichen planus may
occur on male genitalia and buccal mucosa. Atrophic lichen planus (Figure 5) is a rare
form that is characterized by a few well-
demarcated white, pink, or bluish papules,
patches, or plaques with superficial atrophy. Hypertrophic lichen planus (lichen planus
verrucosus; Figure 6) usually occurs on the
extremities, especially the ankles, shins, and
interphalangeal joints, and it tends to be
the most pruritic form. It is often chronic
with residual scarring and pigmentation
when lesions clear. In vesiculobullous lichen
planus (Figure 7), vesicles or bullae develop
from preexisting lesions on the lower limbs,
back, or buttocks, or in the mouth. Erosive/
ulcerative lichen planus lesions develop
within oral lesions or start as waxy semi-
translucent plaques on the soles.

Patients with oral lichen planus often have concomitant manifestations in other extra-
oral sites. A study showed that the vulva and
vagina were also affected in approximately
25 percent of patients with oral lichen planus; involvement of the nails, scalp, esophagus,
or eyes was less common. Oral lichen planus
lesions are often asymptomatic. However,
the condition is occasionally complicated by
extensive painful erosions, leading to a con-
siderable decrease in quality of life. Sensitiv-
ity to heat and a burning sensation may also
occur. Intensive therapy is often required to
reduce these complications.

There are four forms of oral lichen planus:
reticular, atrophic, bullous, and erosive.

phic lesions.

The reticular form is most common and manifests as bilateral, asymptomatic Wickham striae on the oral mucosa (Figure 8) or other parts of the mouth, such as the gingiva, tongue, palate, and lips (Figure 9). The atrophic form causes atrophic changes with erythema of the oral mucosa. The bullous form manifests as fluid-filled vesicles. The erosive form leads to ulcerated, painful, erythematous areas that may contract secondary infection, such as candidiasis. These ulcerated areas may have Wickham striae and occur in one or multiple sites of the mouth. Erosive lichen planus of the gums resembles desquamative gingivitis. Malignant transformation has been reported in men with oral erosive lichen planus lesions.

Lichen planus affecting the genitalia is more common in men. It typically presents on the glans penis and may have an annular pattern (Figure 10). Less commonly, linear, white striae similar to the lesions that typically appear on the vulva and vagina occur on the penis and scrotum. Reticular papules or severe erosions may appear on the vulva and become complicated by urethral stenosis. Dyspareunia and pruritus are common with vulvar and vaginal lesions. Two reports show that more than 50 percent of women with oral lichen planus have undiagnosed vulvar lichen planus.

Approximately 10 percent of patients with lichen planus present with scalp and nail variants. Scalp lesions (lichen planopilaris) are violaceous, scaly, pruritic papules that can progress to scarring alopecia if untreated (Figure 11). Nail involvement...
is characterized by irregular, longitudinal grooving and ridging of the nail plate; thinning of the nail plate; nail pterygium (i.e., cuticular overgrowth); shedding of the nail plate with atrophy of the nail bed; subungual keratosis; longitudinal erythronychia or melanonychia; and subungual hyperpigmentation.7

Diagnosis
Lichen planus can be diagnosed clinically in classic cases, although biopsy is often helpful to confirm the diagnosis and is required for more atypical presentations. A 4-mm punch biopsy should be adequate on the skin or in the mouth. The histology shows a characteristic “saw-tooth” pattern of epidermal hyperplasia; hyperparakeratosis with thickening of the granular cell layer; and vacuolar alteration of the basal layer of the epidermis, with an intense infiltration (mainly T cells) at the dermal-epidermal junction. A 4-mm punch biopsy of perilesional skin for direct immunofluorescence may be added to the workup when bullous lesions, pemphigus, or bullous pemphigoid is present. Tables 2 and 3 present the differential diagnosis of cutaneous and oral lichen planus.

Treatment

be used only by physicians with experience treating severe psoriasis, prescribing oral retinoids, and handling teratogenic medications. Referral to a dermatologist is warranted for patients with severe lichen planus requiring systemic therapy with acitretin or an oral immunosuppressant.

For genital lichen planus lesions, triamcinolone ointment (Triderm) is a good first-line agent. Topical tacrolimus (Protopic) and clobetasol (Temovate) appear to be effective treatments for vulvovaginal erosive lichen planus. Aloe vera gel has been deemed a safe and effective treatment for patients with vulvar lichen planus. Topical lidocaine (Xylocaine) may be used as needed for pain relief, and a water-based lubricant may be used to prevent pain during intercourse.

The scarring alopecia of lichen planopilaris is difficult to reverse. A case series showed that topical high-potency corticosteroids and intrallesional corticosteroids are commonly used.

**ORAL LICHEN PLANUS**

Various treatments have been employed to treat symptomatic oral lichen planus, but complete resolution is difficult to achieve. Table 5 summarizes treatment options for oral lichen planus. Topical corticosteroids are first-line therapy. High-potency topical steroids are the most effective, with response rates up to 75 percent compared with placebo. Topical corticosteroids are also first-line therapy for mucosal erosive lichen planus. High-potency corticosteroids applied to the oral mucosa do not appear to cause significant adrenal suppression, even with relatively long-term use. Systemic corticosteroids, such as oral prednisone, should be considered only for severe, widespread oral lichen planus and for lichen planus involving other mucocutaneous sites.

Table calcineurin inhibitors, such as tacrolimus and pimecrolimus (Elidel), are second-line therapies for oral lichen planus. A comparative study showed that topical tacrolimus is as effective as the high-potency corticosteroid clobetasol in the treatment of oral lichen planus. A randomized controlled trial revealed that pimecrolimus 1% cream effectively treats erosive oral lichen planus with long-lasting therapeutic effects.

In a randomized controlled trial, aloe vera gel was significantly more effective than placebo in the clinical and symptomatologic improvement of oral lichen planus. If topical corticosteroids are ineffective, carbon-dioxide laser evaporation can lead to long-term remission of symptoms, and may be appropriate as first-line therapy in patients with painful oral lichen planus.
